ABSTRACT: Cleaning of air heaters in power plants or recovery boilers has been traditionally done with high pressure water, chemicals or steam. These techniques, while effective on moderate air-side fouling of heat exchange surfaces, are usually ineffective on more tenacious deposits that can develop in coal-fired plants with buildup of fly ash, dust and oil. If these deposits are not cleaned periodically, the heat transfer in the heaters is reduced, which in turn reduces boiler efficiency and increases a unit’s heat rate. Severe fouling on air preheaters and air heaters can even reduce a unit’s Mw output. This paper discusses the recent introduction of a highly effective method of cleaning air heaters utilizing pressurized liquid nitrogen (LN₂). A success story at PPL Generation’s Brunner Island plant illustrates the effectiveness of this new technology.

Air Heater Function and Performance

The role of a plant’s air heater is to improve boiler efficiency by heating the combustion air using available exhaust flue gases. This preheated air accelerates combustion by producing more rapid ignition and also allows the burning of low-grade fuels. For each 50°F increase in boiler inlet air temperature, the boiler efficiency will be increased 1%. Air heaters can increase plant efficiency by up to 10%.

Air heater configurations can vary widely in power plants. Some units utilize a Ljungstrom® type rotary regenerative air heater, or a fixed recuperative tubular air heater. Depending on configuration, many units may also contain a finned tube air preheater immediately after the forced draft fan. The purpose of the air preheater is to keep the primary air heater at a temperature above the dew point or acid saturation point in the primary air heater baskets or coils. If the metal temperature drops below the acid saturation temperature, usually at between 190°F and 230°F, or sometimes at temperatures as high as 260°F then the risk of dew point corrosion damage becomes considerable. If this is not done, deposits of flue gas products will be formed that will corrode the heat transfer surfaces, partially block the air flow, and in extreme cases, it will limit the Mw capacity of the unit.

While air preheaters play a critical role in increasing boiler efficiency, this increase is only effective if the air heater is maintained and kept clean of air-side fouling.

LN₂ Cleaning Technology

NitroLance™, developed by Conco Systems of Verona, Pennsylvania uses pressurized liquid nitrogen to clean various types of heat exchangers and industrial surfaces. It can be used to clean tube internals with small rotating insertable jets, or with larger specialized manifolds for external heat exchanger surfaces including delicate finned heat exchanger tubes.
The typical NitroLance™ process flow is shown in Figure 1. The commercial high purity liquid nitrogen comes from the supplier at -321°F. The NitroLance™ system pressurizes it to between 5,000 PSI and 55,000 PSI. Then, utilizing a temperature controller, the flow is directed while expanding almost 700 times on and into the surface to be cleaned. The controlled flow and temperature is regulated between -160°F and -250°F. The complete system is mounted on a mobile platform that is moved to close proximity of the heat exchangers being cleaned. See Figure 2 for this mobile platform. The NitroLance™ hose and nozzle extend up to 300 feet from the mobile platform while delivering LN2 to the surface being cleaned.

Why is LN2 Cleaning So Effective?

The NitroLance™ cleaning system delivers pressurized liquid nitrogen to the cleaning surface and rapidly removes deposits through three mechanisms of action: thermal expansion, mechanical pressure, and super cooling. (Figure 3)

1. **Thermal Expansion** - As the high density vapor penetrates the cracks and crevices of the fouling deposit, it rapidly converts to a gas expanding nearly 700 times. This rapid expansion, combined with the delivered pressure and cold temperature, causes the fouling deposit to break apart and release its bond with the parent metal.

2. **Mechanical Pressure** - The pressure exerted at the nozzle tip of the NitroLance™ system is regulated from 5,000 PSI to 55,000 PSI based on the equipment being cleaned and fouling characteristics present.

3. **Super Cooling** - The super cool liquid nitrogen (-160°F to -250°F at the nozzle) facilitates embrittlement fracturing of fouling deposits.

**LN2 Cooling of Base Metal**

An evaluation of the effects of LN2 on base metal was performed to examine possible changes to the metal’s grain boundaries and structure, as well as the potential for shrinkage or modifications of mechanical properties that might result from the cold temperatures. Micro-structural observation and micro-hardness measurements were performed on the material before and after LN2 cleaning. As shown in Figure 4 and Figure 5, LN2 cleaning of basic carbon steel induced no micro-structural modifications or changes in the surface micro-hardness of the base metal.

Shrinkage or modifications of the mechanical properties of the base metal is avoided due to the cleaning process being performed at a relatively fast rate of speed (greater than 10 ft/min). Combined with this fast speed and brief contact with the LN2, the base metal only dropped in temperature between 9 and 18°F on average. This small temperature drop induced no notable metal shrinkage and had no notable influence on mechanical properties of the base metal.

**Zero Secondary Waste Streams**

NitroLance™ is unlike traditional water-based methods of cleaning that can produce hundreds of thousands of gallons of effluent. These methods will now require expensive EPA mandated disposal, cleanup and processing. These include air heater cleaning and boiler tube cleaning, boiler fireside cleaning, and many other plant cleaning processes. The benefit of the liquid nitrogen cleaning is that it produces no secondary waste streams. The fouling deposits removed by the NitroLance™ cleaning process can be easily vacuumed up or blown out of the stack during subsequent normal operations. This lack of effluent...
production by NitroLance™ represents a significant cost savings to power plants over traditional water-based methods.

**Critical Path Maintenance Benefit**

Another consideration in addition to the cost savings that zero secondary waste represents is in the area of critical path maintenance activities. NitroLance represented a significantly shorter window needed for cleaning in the fixed length outage at PPL Generation’s Brunner Island Power Plant when compared to water based methods that have been tried without success in the past. The water-based cleaning methods also required extended clean up and disposal activities upon completion of the cleaning phase. The LN₂ cleaning method was successful and it is estimated that several days were saved in the critical path maintenance compared to traditional cleaning methods representing a significant savings to PPL.

**CASE HISTORY of NitroLance™ at PPL Generation**

This LN₂ cleaning was first conducted at PPL Generation’s Montour Power Plant in Washingtonville, PA and then at Brunner Island Power Plant in York Haven, PA. These plants use rotary regenerative Ljungstrom® air preheaters. Upstream of the rotary air heater (on the air side) are finned tube air preheaters which are heated with hot water. See Figure 6 for schematic illustration of the plant's air preheating system.

The finned tube air preheaters often get fouled after a few years of plant operation. Additionally, cleaning of the rotary regenerative air preheater located above causes debris to fall onto the steam coil surface, also requiring them to be cleaned. At PPL’s Brunner Island Unit 3, a 760 Megawatt coal-fired unit, the fouling was due to fly ash deposits, dust/debris, and lube oil that had formed a thick shell over the fin coil surfaces. Since this unit is typically a base-loaded unit it can only come down for maintenance at scheduled outages. Previous attempted cleanings of the air preheater used methods of water, chemicals and detergents. They were ineffective in removing the tenacious deposit of fly ash and oil. The oil portion of the deposit was only on the “B” side and was caused from a bearing seal leak in the unit’s forced draft fan. In operation, this fouling (See Figure 7 for “B” side fouling) created restricted combustion air flow on both “A” and “B” sides. Operators attempted to force more air to the “A” side by the cross-connect air ducting. This partially worked but still created an imbalanced air flow situation. This situation often created a megawatt output reduction during certain weather and operating conditions. As an outage approached for the unit in spring, 2010 the Conco NitroLance™ system was evaluated by PPL engineers and was scheduled for cleaning the fouled “B” side air preheater coils.

**Plant Coordination Meeting**

A site evaluation between Conco engineers and plant personnel concluded that installing a new access door in the ducting adjacent to the air heater would be beneficial. Scaffolding would be placed directly under the horizontal air preheater allowing access to the area to be cleaned. Conco would supply two mobile LN₂ units. Only one mobile unit is normally required, but due to minimal time allocated in this case, two mobile units were required to clean the air heater in only one 12 hour shift. The technicians would be equipped with full safety gear including jump suits, full face respirators (with external air), rubber boots, and cryogenic insulated gloves.

**Cleaning Results**

At the start of the unit’s outage, the Conco technicians went into the air preheater coil ducts and quickly cleaned a portion of the fouled tubes. Figure 8 shows the technicians in protective gear with the
NitroLance™ wand and nozzle removing the deposits. The system’s delivery pressure was carefully adjusted to make sure that the heat exchangers delicate tube fins (0.012 in. thick) were not damaged.

The cleaning of the externally finned heat exchanger was immediate. The fly ash and oil deposits were removed in seconds and a majority of side “B” air preheater was cleaned in only 12 hours. See Figure 9 for results of cleaning an individual coil. The external tube fins are now functional and no damage was done to the fins by the LN₂ cleaning.

**Performance Results**

After the unit was brought back in service, immediate results showed that the airflow blockage on side “B” was significantly reduced and now side “A” and “B” have become airflow balanced. In fact, the airflow pressure drop across the air heater was reduced by half (8 inches H₂O to 4 inches H₂O). Although still higher than original design air flow pressure drop (1.7 inches H₂O), the improvement was significant considering only a portion of the air heater was cleaned due to time limitations. The potential exists for additional improvements by going back in at a future outage and cleaning 100% of the tubes to reach the design pressure drop across the preheater coils. Figure 10 illustrates delta pressures for the air heater before and after the LN₂ cleaning at April’s outage.

Because of the significant improvement of the air heater being brought closer to original design parameters, the plant is considering delaying the replacement of this air heater saving PPL an estimated $2,500,000 to $3,000,000. Additional benefits of this new cleaning approach include additional savings such as:

- Increased boiler efficiency
- Improved unit heat rate
- Megawatt output increase
- Reduced house load
- CO₂ emissions reduction

These benefits were not calculated specifically for this unit due to numerous other maintenance items performed during the outage which also improved the unit’s performance. The heat exchanger cleaning with nitrogen resulted in a significant improvement in unit operation by allowing increased air flow through the unit and balancing the air distribution within the boiler. Additionally, this work was accomplished without increasing the duration of the planned outage.

**Other Applications of LN₂ cleaning**

The cleaning of the steam coil air preheater was so effective that Conco Systems also worked with PPL to test clean sample regenerative air heater baskets. The results from cleaning baskets taken from the Montour plant’s Ljungstrom® unit showed cleaning results that restored the baskets to a very high level of cleanliness. Figure 11 illustrates the before and after results. To clean the rotary air heaters lower end baskets *in-place* during an outage is also possible due to acceptable access heights between the steam coil air heater and most primary air heaters. Soot blowing and other water blasting techniques may now be replaced or supplemented with LN₂ cleaning. The deposits are easily vacuumed up and no waste water removal is needed– thus saving the EPA mandated expense of collection and removal and waste water processing of potentially thousands of gallons of effluent.
Additionally, this innovative cleaning technique was recently tested boiler superheater tubes at PPL’s J. E. Corette Power Plant in Billings, Montana. The results shown in Figures 12 (before cleaning) and Figure 13 (after cleaning) indicate efficient cleaning on the deposits of ash and slag while not damaging the parent tube material.

Overall, nitrogen cleaning with NitroLance™ provides a new and significant technique for cleaning various deposits in power plants and industrial facilities without damaging the parent metal. The types of deposits that are easily removable include fly ash, slag, carbon/soot, sulphur, and various oils.

Conclusion

Air preheaters provide a critical role in boosting boiler efficiency, but when compromised with air-side fouling, can actually reduce plant output. Historically, air preheater cleaning has been accomplished utilizing water, steam or chemicals, which produce a significant volume of effluent that require tedious handling and disposal at considerable cost. The recent introduction of new technology utilizing pressurized liquid nitrogen not only speeds the cleaning process, but does it without producing secondary waste streams, saving power plants time and money. In addition to air preheaters, liquid nitrogen also appears to be an optimal choice for many other applications within power generation and industrial facilities where its speed of deposit removal and zero-waste benefit is advantageous.
